VULTR HACKATHON · BLAST RADIUS ZERO

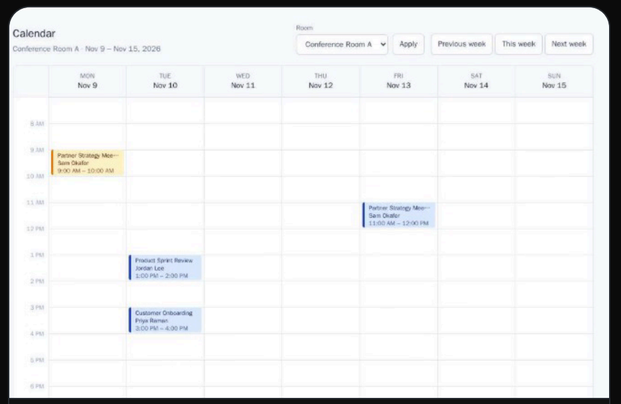

Reprobe

Reproduce the bug.
Verify the fix.

An agent that follows your bug report in a real browser, inside a disposable sandbox on Vultr, and comes back with proof.

● Reproduced

● Not reproduced

▼ Run history · 2 runs

● Not reproduced	Nov 8, 2026, 6:11 AM	https://roompilot-production.up.railway.app	Viewing
● Reproduced	Nov 8, 2026, 6:00 AM	https://roompilot-production.up.railway.app	View run

THE PROBLEM

Every bug gets checked by hand. Twice, or more.

A ticket comes in with steps, a screenshot or a recording. Before anyone trusts it, someone signs in, sets up the data and clicks through every step. Then they do it all again after the fix.

CHECK 1

Is it still happening?

Old tickets go stale. Nobody knows if the bug is real until someone walks the steps.

CHECK 2

Did the fix work?

The same steps again, by hand, after the deploy, and again the next time someone touches that code.

WHAT REPROBE DOES

Give it the bug report and a link. Get a verdict with proof.

1 · READ

Written steps, screenshots and screen recordings become a numbered plan. Every step cites its source.

2 · SANDBOX

A fresh browser starts in a disposable gVisor container that can only reach the app under test.

3 · RUN

The agent follows the plan in order, types like a person, and reads form values as well as page text.

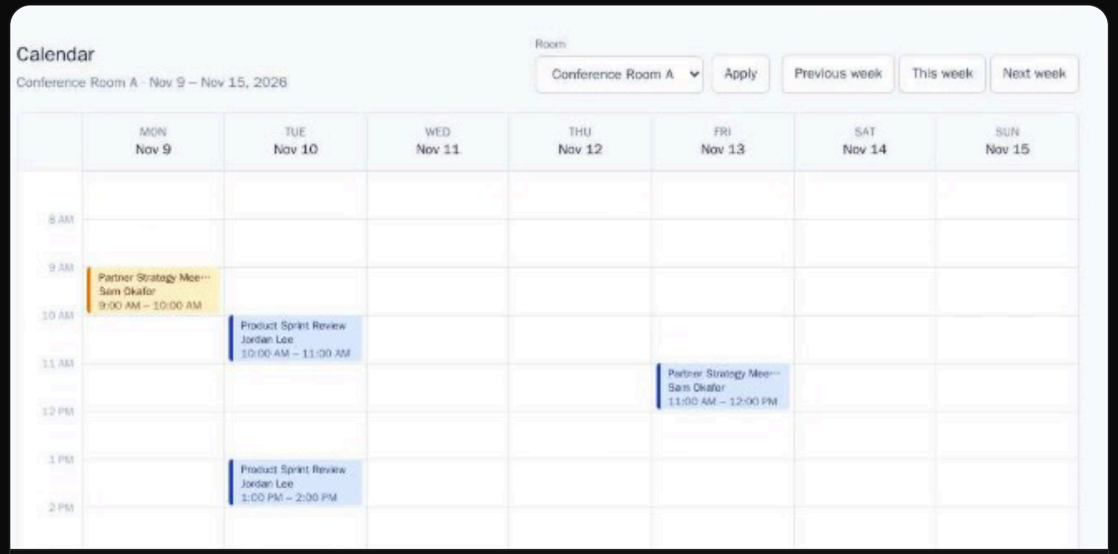

4 · PROVE

Reproduced, not reproduced or inconclusive, with expected vs. observed, the step, a recording and the action log.

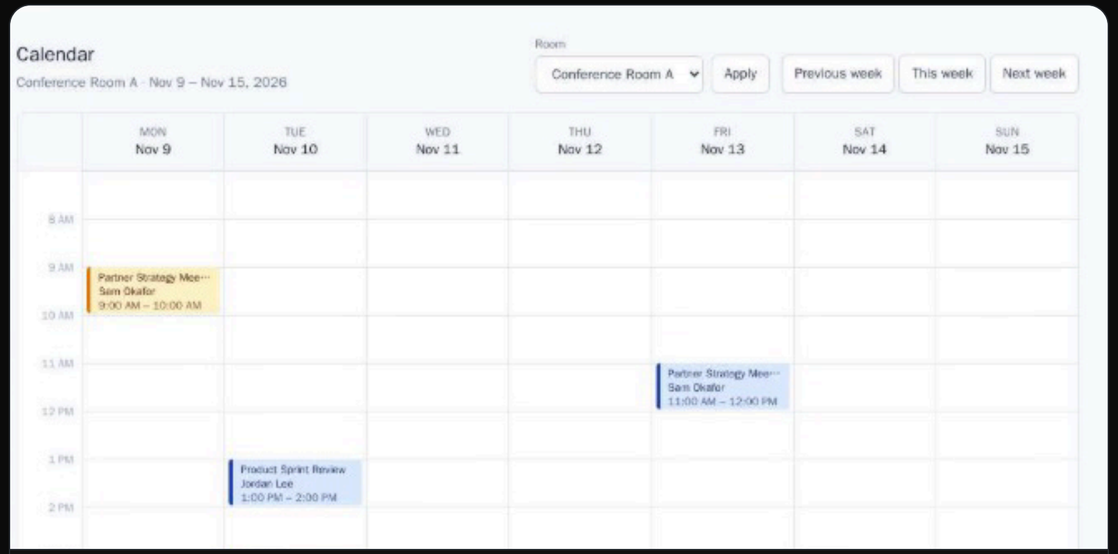

You can watch live, take over the browser, answer the agent's questions, or stop the run. **Run again** repeats the same check with one click and keeps every result in the bug's history.

DEMO · ROOMPILOT BUG RP-214

One bug, two checks, opposite results.

● Check 1 · Reproduced — 47 s · meeting in both slots

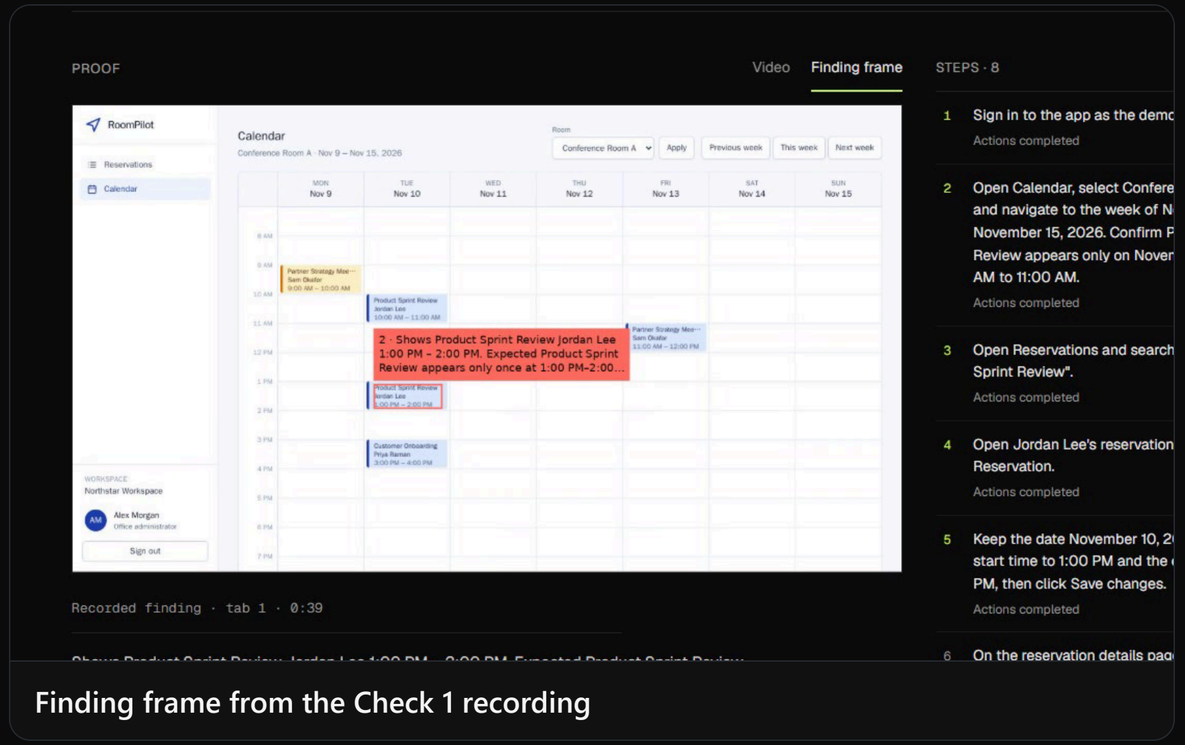

● Check 2 · Not reproduced — 39 s · after the fix

PROOF YOU CAN TRUST

It can't just describe the bug back to you.

Finding frame from the Check 1 recording

- The verdict tool rejects any observed value that isn't on the page word for word.
- Expected vs. observed, plus the step where it showed.
- A recording of every tab with click markers, and the full action log.
- Plan steps cite where they came from: "written step 5", "video 00:07".

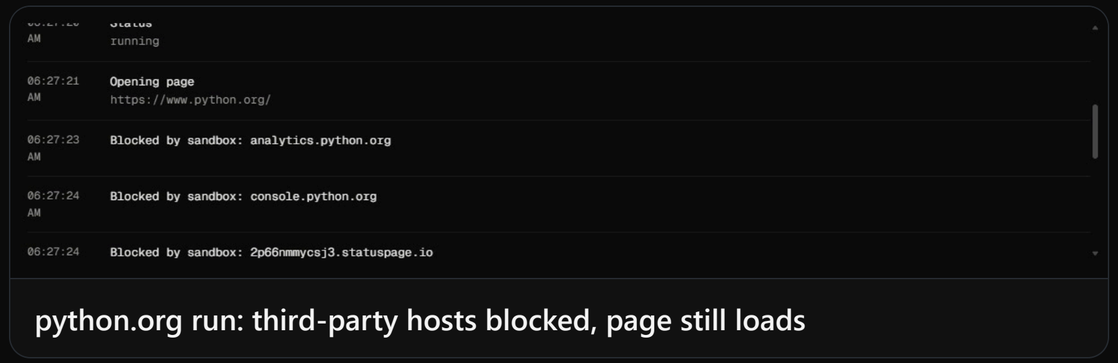

CONTAINMENT · BLAST RADIUS ZERO

Every run is contained, capped and destroyed.

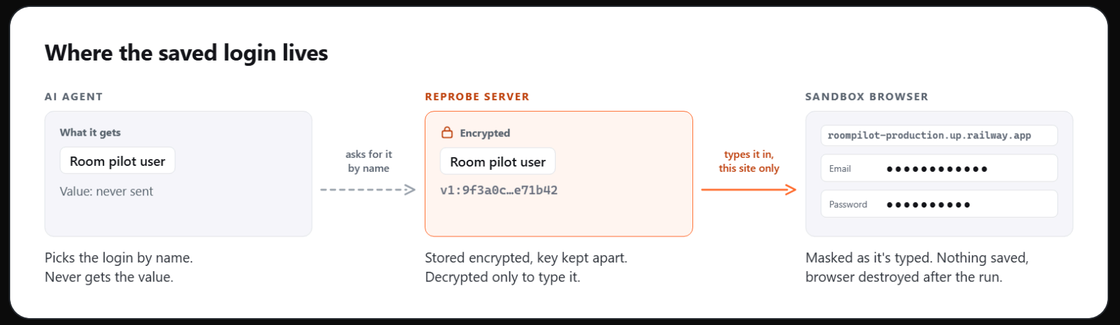

REQUIREMENT	HOW REPROBE ENFORCES IT
Process isolation	Each run gets its own Docker container under gVisor (runsc). Only Chromium runs inside. No capabilities, no-new-privileges, read-only root.
Resource limits	1.5 vCPU, 1536 MB memory, 256 processes, a 900-second container cap and a 600-second agent limit.
Lifecycle discipline	The container and its firewall rule are removed after every run, on success, failure, cancel or timeout. A reaper runs every 5 minutes.
Network	Only the target host on ports 80/443, plus read-only files from a fixed CDN list. Everything else is blocked and logged.
Secret hygiene	No API keys, env vars or mounts in the sandbox. The agent and the inference key stay on the VM and drive Chromium over the Playwright protocol.

CONTAINMENT, ON SCREEN

What the sandbox blocks, and where logins live.

python.org run: third-party hosts blocked, page still loads

Saved test logins are AES-256-GCM encrypted on the server, offered only on their allowed domain, never shown to the AI, and typed only into a focused field on the target site, masked.

ARCHITECTURE

One Vultr VM. One throwaway sandbox per run.

You
Browser, HTTPS

VULTR CLOUD COMPUTE · SEATTLE

Caddy → FastAPI app
Accounts, runs, evidence, reports.
Encrypted credential store.

Navgent agent
LangChain deep agents + Playwright.
Plan, act, verify, report_verdict.

sandboxctl (root-owned)
The only privileged step: start, stop, reap.
Owns every container flag and firewall rule.

→ Playwright

Sandbox container · gVisor
Chromium + Playwright server only.
1.5 vCPU · 1536 MB · 900 s.
No keys, no mounts, no env.
Reaches the target host only.

Vultr Serverless Inference
glm-5.3 for the agent loop.
glm-5.3-flash for evidence.

App under test
e.g. RoomPilot.
Only host the sandbox can reach.

VULTR SERVICES

Built entirely on Vultr.

CLOUD COMPUTE

One VM runs it all

vhp-4c-8gb-amd in Seattle, Ubuntu 24.04: the web app, the agent, Docker with gVisor, and Caddy for HTTPS.

FIREWALL

Three open ports

Firewall group "reprobe": only TCP 22, 80 and 443 are reachable from the internet. Sandboxes get per-run iptables rules on top.

SERVERLESS INFERENCE

Every model call

glm-5.3 drives the agent loop. glm-5.3-flash reads screenshots and video frames into the plan. No other model provider is configured.

WHY IT MATTERS

Known bugs stay checked. Fixes get verified.

- QA and developers stop re-walking the same steps for every stale ticket and every fix.
- Each verdict comes with proof a reviewer can open: recording, expected vs. observed, the step.
- A bug's checks live in its run history. One click reruns them after the next change.
- The agent never holds secrets and can't reach anything but the app it's testing.
